Joint work with Yong-Jin Liu and Kim-Chuan Toh

Let $\Re^{n_{1} \times n_{2}}$ be the linear space of all $n_{1} \times n_{2}$ real matrices, not necessarily square or symmetric.

- Trace product:

$$
\langle X, Y\rangle=\sum_{i, j} X_{i j} Y_{j i}=\operatorname{Trace}\left(X^{T} Y\right)
$$

- The Frobenius norm: $\|X\|=\sqrt{\langle X, X\rangle}$.
- The nuclear norm: $\|X\|_{*}=\sum_{i=1}^{\min \left\{n_{1}, n_{2}\right\}} \sigma_{i}$, where $\sigma_{i}, 1 \leq i \leq \min \left\{n_{1}, n_{2}\right\}$ are the singular values of $X$.

Given a linear mapping $\mathcal{A}: \Re^{n_{1} \times n_{2}} \rightarrow \Re^{m}$ and $b \in \Re^{m}$.
Consider the following nuclear norm minimization problem with linear equality and second order cone (SOC) constraints:

$$
\begin{aligned}
(\mathrm{P}) \quad \min & \|X\|_{*} \\
& \text { s.t. } \\
& \mathcal{A}(X) \in b+\mathcal{Q},
\end{aligned}
$$

where $\mathcal{Q}:=\{0\}^{m_{1}} \times \mathcal{K}^{m_{2}}$ and $\mathcal{K}^{m_{2}}$ denotes the SOC of dimension $m_{2}$. Here, $m=m_{1}+m_{2}$.

The problem ( P ) is the convex relaxation ${ }^{\mathrm{a}}$ of the rank minimization problem with/without noise arising in many fields of engineering and science.

The rank minimization problem is:

$$
\begin{array}{ll}
\min & \operatorname{Rank}(X) \\
\text { s.t. } & \mathcal{A}(X)=b .
\end{array}
$$

${ }^{\text {a Recht, B., Fazel, M. and Parrilo, P.A., Guaranteed minimum-rank }}$ solutions of linear matrix equations via nuclear norm minimization, preprint.

A special case is the matrix completion problem, which has the form:

$$
\begin{array}{ll}
\min & \operatorname{rank}(X) \\
\text { s.t. } & X_{i j}=M_{i j},(i, j) \in \Omega,
\end{array}
$$

where $M$ is the unknown matrix with $m$ available sampled entries, and $\Omega$ is a set of index pairs $(i, j)$ of cardinality $m$.

- In this case, $\mathcal{A}(X)=X_{\Omega}$, where $X_{\Omega} \in \Re^{|\Omega|}$ is the vector consisting of elements selected from $X$ whose indices are in $\Omega$.
- The rank minimization problem is NP-hard in general and computationally hard to solve.
Question: How can we get the matrix with the minimum rank of the rank minimization problem?
- A novel and tractable approach ${ }^{\mathrm{a}}$ is to consider solving its convex relaxation problem:

$$
\begin{aligned}
(\mathrm{CRP}) & \text { min } \\
& \|X\|_{*} \\
\text { s.t. } & \|b-\mathcal{A}(X)\| \leq \delta,
\end{aligned}
$$

where $\delta \geq 0$ estimates the uncertainty about the observation $b$.
${ }^{\text {a }}$ Candès, E.J. and Recht, B., Exact matrix completion via convex optimization, preprint.

Some works ${ }^{\mathrm{a}, \mathrm{b}}$ consider solving the Lagrangian version of (CRP):

$$
\min _{X \in \Re^{n_{1} \times n_{2}}} \frac{1}{2}\|\mathcal{A}(X)-b\|^{2}+\mu\|X\|_{*}
$$

- Although (CRP) and its Lagrangian version are equivalent whenever $\delta$ and $\mu$ obey some special relationship, it is generally hard to find the relationship.

[^0]One obvious approach for $(\mathrm{P})$ is to consider solving its semidefinite programming (SDP) reformulation:

$$
\begin{array}{ll}
\min & \left(\operatorname{Tr}\left(W_{1}\right)+\operatorname{Tr}\left(W_{2}\right)\right) / 2 \\
\text { s.t. } & \mathcal{A}(X) \in b+\mathcal{Q} \\
& {\left[\begin{array}{cc}
W_{1} & X \\
X^{T} & W_{2}
\end{array}\right] \succeq 0 .}
\end{array}
$$

But, the problem is:
The above approach makes the SDP more difficult since it greatly enlarges the dimension of problem.
This suggests that other methods are needed to solve (P) directly.

## Related Algorithms:

- The projected subgradient method [Recht, Fazel and Parrilo]: Convergence?
- The singular value thresholding (SVT) algorithm [Cai, Candès and Shen]: It is in the class of penalty methods so that it requires large parameters.
- An accelerated proximal gradient (APG) algorithm [Toh and Yun]: It is applied to the Lagrangian version of (CRP).
- Fixed point method and Bregman iterative method [Ma, Goldfarb and Chen]: They are also applied to the Lagrangian version of (CRP).

Our work: Three classes of proximal point algorithms (PPA) in the primal, dual and primal-dual forms.

- The Lagrangian function of $(\mathrm{P})$ in the extended form:

$$
l(X, y):= \begin{cases}\|X\|_{*}+\langle y, b-\mathcal{A}(X)\rangle & \text { if } y \in \mathcal{Q}^{*} \\ -\infty & \text { if } y \notin \mathcal{Q}^{*}\end{cases}
$$

where $\mathcal{Q}^{*}$ is the dual cone of $\mathcal{Q}$.

- The dual problem of (P):
(D) $\max _{y \in \Re^{m}}\left\{g(y):=\inf _{X \in \Re^{n_{1} \times n_{2}}} l(X, y)\right\}$.
- The primal form.

The primal PPA is the application of the general proximal point method to $(\mathrm{P})$. That is,

$$
X^{k+1} \approx \arg \min _{X \in \Re^{n_{1} \times n_{2}}}\left\{f(X)+\frac{1}{2 \lambda_{k}}\left\|X-X^{k}\right\|^{2}\right\}
$$

where $f$ is the convex function defined by

$$
f(X)=\sup _{y \in \Re^{m}} l(X, y) .
$$

- How to approximately get $X^{k+1}$ ?

For given $\lambda>0$, let $\Theta_{\lambda}(y ; X)$ be defined by

$$
\Theta_{\lambda}(y ; X)=\langle b, y\rangle-\frac{1}{2 \lambda}\left(\left\|\mathcal{P}_{\lambda}\left[X+\lambda \mathcal{A}^{*}(y)\right]\right\|^{2}-\|X\|^{2}\right)
$$

where $(y, X) \in \Re^{m} \times \Re^{n_{1} \times n_{2}}$ and for any $\lambda>0$ and $X \in \Re^{n_{1} \times n_{2}}, \mathcal{P}_{\lambda}(X)$ is the unique optimal solution to

$$
\min _{Y \in \Re \Re^{n_{1} \times n_{2}}} \lambda\|Y\|_{*}+\frac{1}{2}\|Y-X\|^{2} .
$$

Let $X$ be of rank $r$ and have the following singular value decomposition:

$$
X=U \Sigma V^{T}, \quad \Sigma=\operatorname{diag}\left(\left\{\sigma_{i}\right\}_{1 \leq i \leq r}\right)
$$

where $U \in \Re^{n_{1} \times r}$ and $V \in \Re^{n_{2} \times r}$ have orthonormal columns, respectively, and the positive singular values $\sigma_{i}$ are arranged in descending order. Then,

$$
\mathcal{P}_{\lambda}(X)=U \operatorname{diag}\left(\max \left\{\sigma_{i}-\lambda, 0\right\}\right) V^{T} .
$$

- The function $\Theta_{\lambda}(y ; X)$ is continuously differentiable.

For any given $X \in \Re^{n_{1} \times n_{2}}$, we have

$$
\nabla_{y} \Theta_{\lambda}(y ; X)=b-\mathcal{A} \mathcal{P}_{\lambda}\left(X+\lambda \mathcal{A}^{*}(y)\right)
$$

- For any given $X \in \Re^{n_{1} \times n_{2}}, \nabla_{y} \Theta_{\lambda}(\cdot, X)$ is globally Lipschitz continuous.
- The primal PPA

For given $X^{0} \in \Re^{n_{1} \times n_{2}}, \lambda_{0}>0$, and $\rho>1$, the primal PPA for solving problem ( P ) generates sequences $\left\{y^{k}\right\} \subset \Re^{m}$ and $\left\{X^{k}\right\} \subset \Re^{n_{1} \times n_{2}}$ for $k=0,1,2, \ldots$

$$
\left\{\begin{array}{l}
y^{k+1} \approx \arg \max _{y \in \mathcal{Q}^{*}} \Theta_{\lambda_{k}}\left(y ; X^{k}\right), \\
X^{k+1}=\mathcal{P}_{\lambda_{k}}\left[X^{k}+\lambda_{k} \mathcal{A}^{*}\left(y^{k+1}\right)\right], \\
\lambda_{k+1}=\rho \lambda_{k} \text { or } \lambda_{k+1}=\lambda_{k} .
\end{array}\right.
$$

- Connection to the SVT algorithm

For a special case of $(\mathrm{P})$ without the SOC constraints, from the primal PPA, if $X^{0}=0$ and $\lambda_{0}=\lambda^{-1}>0$, then $X^{1}$ is exactly the solution to the following regularized problem:

$$
\begin{array}{ll}
\min & \lambda\|X\|_{*}+\frac{1}{2}\|X\|^{2} \\
\text { s.t. } & \mathcal{A}(X)=b .
\end{array}
$$

The SVT algorithm by [Cai, Candès and Shen] solves it by applying the gradient method to its dual problem and it is just one-step of the primal PPA.

- The dual form.

The dual PPA is the application of the general proximal point method to the dual problem (D), instead of (P). The sequence $\left\{y^{k}\right\} \subset \mathcal{Q}^{*}$ is generated by the dual PPA as follows:

$$
y^{k+1} \approx \underset{y \in \mathbb{R}^{m}}{\operatorname{argmax}}\left\{g(y)-\frac{1}{2 \lambda_{k}}\left\|y-y^{k}\right\|^{2}\right\}
$$

Recall that $g(y)=\inf _{X \in \Re^{n_{1} \times n_{2}}} l(X, y)$.

- How can we approximately obtain $y^{k+1}$ ?

For given $\lambda>0$, let $\Psi_{\lambda}(X ; y)$ be defined by

$$
\Psi_{\lambda}(X ; y)=\|X\|_{*}+\frac{1}{2 \lambda}\left[\left\|\Pi_{Q^{*}}[y+\lambda(b-\mathcal{A}(X))]\right\|^{2}-\|y\|^{2}\right],
$$

where $(X, y) \in \Re^{n_{1} \times n_{2}} \times \Re^{m}$ and for any $\lambda>0$ and $x \in \Re^{m}, \Pi_{\mathcal{Q}^{*}}(x)$ is the unique optimal solution to

$$
\min _{z \in \mathcal{Q}^{*}} \frac{1}{2}\|z-x\|^{2}
$$

For any $x=\left(x^{1} ; x^{2}\right) \in \Re^{m_{1}} \times \Re^{m_{2}}$, one has

$$
\Pi_{\mathcal{Q}^{*}}(x)=\left(x^{1} ; \Pi_{\mathcal{K}^{m_{2}}}\left(x^{2}\right)\right) .
$$

where $\Pi_{\mathcal{K}^{m_{2}}}\left(x^{2}\right)$ is given by

$$
\Pi_{\mathcal{K}^{m_{2}}}\left(x^{2}\right)= \begin{cases}\frac{1}{2}\left(1+\frac{x_{0}^{2}}{\left\|x^{2}\right\|}\right)\left(\left\|\overline{x^{2}}\right\| ; \overline{x^{2}}\right) & \text { if }\left|x_{0}^{2}\right|<\left\|\overline{x^{2}}\right\| \\ \left(x_{0}^{2} ; \overline{x^{2}}\right) & \text { if }\left\|\overline{x^{2}}\right\| \leq x_{0}^{2} \\ 0 & \text { if }\left\|\overline{x^{2}}\right\| \leq-x_{0}^{2}\end{cases}
$$

here, $x^{2}=\left(x_{0}^{2}, \overline{x^{2}}\right) \in \Re \times \Re^{m_{2}-1}$.

- The dual PPA

For given $y^{0} \in \Re^{m}, \lambda_{0}>0$, and $\rho>1$, the dual PPA for solving problem ( P ) and ( D ) generates sequences $\left\{y^{k}\right\} \subset \Re^{m}$ and $\left\{X^{k}\right\} \subset \Re^{n_{1} \times n_{2}}$ for $k=0,1,2, \ldots$

$$
\begin{aligned}
& X^{k+1} \approx \arg \min _{X \in \mathcal{R}^{n_{1} \times n_{2}}} \Psi_{\lambda_{k}}\left(X ; y^{k}\right), \\
& y^{k+1}=\Pi_{\mathcal{Q}^{*}}\left[y^{k}+\lambda_{k}\left(b-\mathcal{A}\left(X^{k+1}\right)\right)\right], \\
& \lambda_{k+1}=\rho \lambda_{k} \text { or } \lambda_{k+1}=\lambda_{k} .
\end{aligned}
$$

For the special case of $(\mathrm{P})$ with equality constraints only, then with $y^{0}=0$,

$$
y^{1}=\lambda_{0}\left(b-\mathcal{A}\left(X^{1}\right)\right),
$$

where $X^{1}$ (approximately) solves the following penalized problem:

$$
\min _{X \in \Re^{n_{1} \times n_{2}}}\left\{\frac{1}{2}\|\mathcal{A}(X)-b\|^{2}+\lambda_{0}^{-1}\|X\|_{*}\right\} .
$$

Again, this says that $y^{1}$ is the result for one-step of the dual PPA.

- Connection to the Bregman iterative method

The Bregman iterative method by [Ma, Goldfarb and Chen] for solving the special case of $(\mathrm{P})$ without noise can be described as:

$$
\left\{\begin{array}{l}
b^{k+1}=b^{k}+\left(b-\mathcal{A}\left(X^{k}\right)\right) \\
X^{k+1}=\arg \min _{X \in \Re^{n_{1} \times n_{2}}}\left\{\frac{1}{2}\left\|\mathcal{A}(X)-b^{k+1}\right\|^{2}+\mu\|X\|_{*}\right\}
\end{array}\right.
$$

for some fixed $\mu>0$. By noting that $b^{k+1}=\mu y^{k+1}$ with $\mu=\lambda_{k}{ }^{-1}$, we know that the Bregman iterative method is actually a special case of the dual PPA with $\lambda_{k} \equiv \mu^{-1}$.

- The primal-dual form.

The primal-dual PPA is the application of the general proximal point method to the monotone operator corresponding to the convex-concave Lagrangian function $l$, i.e.,

$$
\begin{aligned}
& \left(X^{k+1}, y^{k+1}\right) \approx \min _{X \in \Re^{n_{1} \times n_{2}}} \max _{y \in \Re^{m}}\{l(X, y)+ \\
& \left.\quad+\frac{1}{2 \lambda_{k}}\left\|X-X^{k}\right\|^{2}-\frac{1}{2 \lambda_{k}}\left\|y-y^{k}\right\|^{2}\right\} .
\end{aligned}
$$

- How to get an approximation solution $\left(X^{k+1}, y^{k+1}\right)$ ?
- The primal-dual PPA-I

For given $\left(X^{0}, y^{0}\right) \in \Re^{n_{1} \times n_{2}} \times \Re^{m}, \lambda_{0}>0$, and $\rho>1$, the primal-dual PPA-I for solving problem (P) and (D) generates sequences $\left\{\left(X^{k}, y^{k}\right)\right\} \subset \Re^{n_{1} \times n_{2}} \times \Re^{m}$ for $k=0,1,2, \ldots$

$$
\left\{\begin{array}{l}
y^{k+1} \approx \arg \max _{y \in \mathcal{Q}^{*}}\left\{\Theta_{\lambda_{k}}\left(y ; X^{k}\right)+\frac{1}{2 \lambda_{k}}\left\|y-y^{k}\right\|^{2}\right\}, \\
X^{k+1}=\mathcal{P}_{\lambda_{k}}\left[X^{k}+\lambda_{k} \mathcal{A}^{*}\left(y^{k+1}\right)\right], \\
\lambda_{k+1}=\rho \lambda_{k} \text { or } \lambda_{k+1}=\lambda_{k} .
\end{array}\right.
$$

- The primal-dual PPA-II

For given $\left(X^{0}, y^{0}\right) \in \Re^{n_{1} \times n_{2}} \times \Re^{m}, \lambda_{0}>0$, and $\rho>1$, the primal-dual PPA-II for solving problem (P) and (D) generates sequences $\left\{\left(X^{k}, y^{k}\right)\right\} \subset \Re^{n_{1} \times n_{2}} \times \Re^{m}$ for $k=0,1,2, \ldots$

$$
\begin{aligned}
& X^{k+1} \approx \arg \min _{X \in \Re^{n_{1} \times n_{2}}}\left\{\Psi_{\lambda_{k}}\left(X ; y^{k}\right)+\frac{1}{2 \lambda_{k}}\left\|X-X^{k}\right\|^{2}\right\}, \\
& y^{k+1}=\Pi_{\mathcal{Q}^{*}}\left[y^{k}+\lambda_{k}\left(b-\mathcal{A}\left(X^{k+1}\right)\right)\right], \\
& \lambda_{k+1}=\rho \lambda_{k} \text { or } \lambda_{k+1}=\lambda_{k} .
\end{aligned}
$$

- First-order methods for the inner problems

We consider the gradient projection method (GPM) to solve the inner problems of the primal PPA and the primal-dual PPA-I, which have the form:

$$
(\mathrm{SP} 1) \min \left\{h(y): y \in \mathcal{Q}^{*}\right\},
$$

where $h$ is continuously differentiable and its gradient is Lipshitz continuous with modulus $L_{h}>0$.

For given $y^{0} \in \mathcal{Q}^{*}$, the GPM for solving (SP1) is:

$$
y^{k+1}=\Pi_{\mathcal{Q}^{*}}\left[y^{k}-\alpha_{k} \nabla h\left(y^{k}\right)\right],
$$

where $\alpha_{k}>0$ is the steplength to be decided in various rules, e.g., the Armijo line search rule or the constant steplength rule:

$$
\alpha_{k}=s \quad \text { with } s \in\left(0,2 / L_{h}\right) .
$$

- The GPM has an iteration complexity of $O\left(L_{h} / \varepsilon\right)$ for achieving $\varepsilon$-optimality for any $\varepsilon>0$.
- An accelerated proximal gradient method

We consider an accelerated proximal gradient (APG) method to solve the inner problems of the primal PPA and the primal-dual PPA-II, which have the form:

$$
\text { (SP2) } \min _{X \in \Re^{n_{1} \times n_{2}}}\left\{H(X):=\|X\|_{*}+h(X)\right\},
$$

where $h$ are proper, convex, continuously differentiable on $\Re^{n_{1} \times n_{2}}$, and $\nabla h$ are globally Lipschitz continuous with modulus $L_{h}>0$.

- The APG algorithm

For given $\tau_{0}=\tau_{-1}=1$ and $X^{0}=X^{-1} \in \Re^{n_{1} \times n_{2}}$, the APG algorithm applied to solving (SP2) can be expressed as:

$$
\left\{\begin{aligned}
\widehat{X}^{k} & =X^{k}+\tau_{k}^{-1}\left(\tau_{k-1}-1\right)\left(X^{k}-X^{k-1}\right), \\
X^{k+1} & =\mathcal{P}_{L_{h}^{-1}}\left[\widehat{X}^{k}-L_{h}^{-1} \nabla h\left(\widehat{X}^{k}\right)\right], \\
\tau_{k+1} & =\left(\sqrt{1+4 \tau_{k}^{2}}+1\right) / 2,
\end{aligned}\right.
$$

where $L_{h}$ is the Lipschitz modulus of $h$.

- The APG algorithm has an attractive iteration complexity of $O\left(\sqrt{L_{h} / \varepsilon}\right)$ for achieving $\varepsilon$-optimality for any $\varepsilon>0$.
© Why we do not apply the APG algorithm to the inner problems of the primal PPA and the primal-dual PPA-I?
The reason is that it requires two SVDs in each iteration. Two SVDs per iteration is too expensive.

Numerical results

- Stopping Criteria:

$$
\frac{\left\|b-\mathcal{A}\left(X^{k}\right)\right\|}{\max \{1,\|b\|\}}<5 \times 10^{-5}
$$

or

$$
\frac{\left|\left\|b-\mathcal{A}\left(X^{k}\right)\right\|-\left\|b-\mathcal{A}\left(X^{k-1}\right)\right\|\right|}{\max \{1,\|b\|\}}<5 \times 10^{-5} .
$$

- PC: Intel Xeon 3.20 GHz with 4GB, Linux and Matlab (Version 7.6).
- PROPACK package to compute partial SVDs.

| $100000 / 0.10$ | 11994813 | 10 | 6 | $1.34 \mathrm{e}-02$ | 43 | 10 | $5.42 \mathrm{e}+02$ | $4.53 \mathrm{e}-02$ |

## Remarks:

- Comparing the performances of the primal PPA and the dual PPA for random matrix completion problems without and with noisy data, we observe that the dual PPA outperforms the primal PPA.
* In our experiments, we observe that the performance of the primal-dual PPA-I is similar to that of the primal PPA, and the performance of the primal-dual PPA-II is also similar to that of the dual PPA.
