Background: semantic and syntactic enrichment

- **Semantic enrichment** (e.g. complement coercion):
 - *The boy **started** the puzzle* means something like “the boy started *doing* the puzzle”
- **Syntactic enrichment** (e.g. intensional transitives):
 - *The boy **wanted** the puzzle* means something like “the boy wanted *to have* the puzzle”
- Semantic enrichment involves changing the denotation of *puzzle* (Pustejovsky, 1991 [*Cognition*], among others), but syntactic enrichment involves inserting a silent verb (Harley, 2003 [*LIT*]; Pykkänen, 2008 [*Lang Ling Compass*]; among others)
- **Research question**: do syntactic and semantic enrichment have different consequences for online processing?
 - Detecting *semantic* mismatch between a verb and its argument is known to engender processing cost (Traxler et al., 2002 [*JML*], among others), as evidenced by slower reading times for objects that require enrichment
 - Enrichment: “The boy started the puzzle”
 - No-enrichment: “The boy saw the puzzle”
 - Syntactic enrichment also costly (Delogu et al., 2010 [*JML*])
 - Are the patterns of processing costs qualitatively different?

Design (based on Traxler et al., 2002)

- 48 sentences, manipulating Verb Type (3: aspectual, intensional, neutral) and Noun Type (2: event-denoting, entity-denoting),
 - Neutral verbs (which can take an event or entity complement) should never trigger enrichment
 - Aspectual verbs should trigger enrichment for entity-denoting nouns (as evidenced by slower reading after event verbs than after neutral verbs) but not event-denoting nouns
 - Intensional verbs might always trigger enrichment

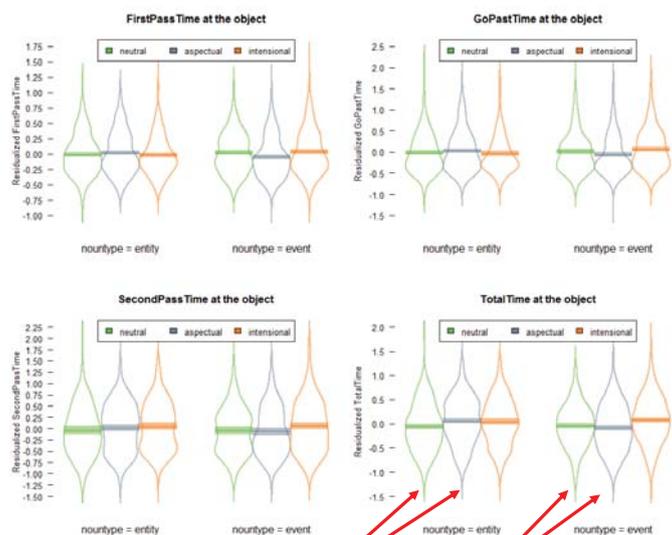

The young boy

{*started*_{ASPECTUAL}/*wanted*_{INTENSIONAL}/*noticed*_{NEUTRAL}} a {*fight*_{EVENT}/*puzzle*_{ENTITY}} and his mum found out.

- Eye-tracking while reading (205 unrelated fillers, comprehension questions on all trials)
- Object surprisal estimated using Google Books trigrams; these values are included as covariates in the statistical models (see also Delogu, 2013 [*CUNY conference*])
- Reading times residualized using linear mixed-effects models

Results: Object region (N=47 native English speakers)

Violin plots of residual reading times for each measure. Shaded areas represent 95% confidence intervals (from mixed-effects model, normal bootstrap with 100 replicates) of the mean.

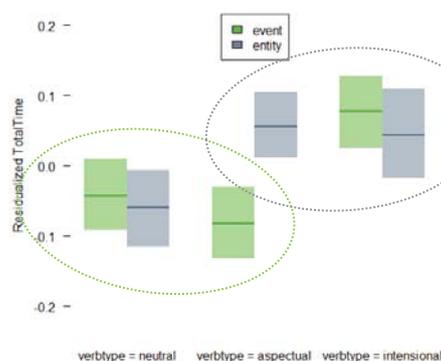

Entity nouns read more slowly after aspectual verbs compared to neutral verbs

No such slowdown for event nouns

Intensional verbs lead to slowdowns for both noun types

TotalTime at the object (zoomed in)

With event nouns, aspectual verbs pattern with neutral verbs (no enrichment).

With entity nouns, aspectual verbs pattern with intensional verbs (enrichment).

Discussion

- Semantic and syntactic enrichment may apply differently: semantic enrichment (complement coercion) occurred in limited contexts but syntactic enrichment (covert verb insertion) may have applied across the board
- However, when enrichment did occur, there was not evidence that semantic and syntactic enrichment engendered qualitatively different eye movement patterns
- Future directions:
 - Probing for qualitative differences using ERPs and structural priming;
 - Examining other types of verbs (e.g. verbs that select for propositions)

Results: Verb region

- No effects of semantic enrichment (aspectual vs. neutral verbs)
- Syntactic enrichment: late measures (regressions in, total reading time) suggest that event-denoting nouns in intensional verb contexts triggered more processing difficulty entity-denoting nouns in intensional verb contexts did
